Suspected Adverse Drug Reaction (ADR) Report

Pharmacovigilance case practice | Report type: **Initial** | Prepared by: **Abarna**

Fictional case created for internship practice. Not a real patient report.

SECTION A - PATIENT DETAILS

Patient initials	R.K. (identity withheld)
Age / Gender	42 years / Female
Weight	58 kg
Height	160 cm

SECTION B - SUSPECTED ADVERSE REACTION

Reaction onset	Day 3 after starting treatment
Reaction stop date	Day 6 (3 days after drug withdrawal)
Description	Itchy raised red rash (urticaria) on the trunk and arms with mild facial swelling. No breathing difficulty, no fever, no hypotension.
Investigations	Vitals stable; SpO2 98% on room air; CBC and liver function tests within normal limits.
Relevant history	Recurrent sinusitis; no known drug allergy; no previous history of urticaria.
Seriousness	Non-serious (no death, hospitalisation, disability or life-threatening event; ICH E2A criteria not met).
Outcome	Recovered / resolved

SECTION C - SUSPECTED AND CONCOMITANT MEDICATION

Drug	Role	Dose / route	Start	Stop	Indication
Amoxicillin + Clavulanic acid	Suspect	625 mg, oral, twice daily	Day 0	Day 3	Acute bacterial sinusitis
Paracetamol	Concomitant	500 mg, oral, as needed	Day 0	Day 2	Headache

Action taken	Suspect drug withdrawn on Day 3; antihistamine (cetirizine 10 mg) given for 3 days.
Dechallenge	Positive - rash resolved within 3 days of stopping the drug.
Rechallenge	Not done (not ethical or necessary).
Other medication	Paracetamol only, used for headache; no new drugs or foods started before the rash.

CAUSALITY ASSESSMENT

WHO-UMC category	**PROBABLE / LIKELY**
Reasoning	Time to onset is plausible (Day 3); the reaction is a known effect of penicillin-class drugs; it improved on withdrawal (positive dechallenge); other causes (infection, other drugs, food) are unlikely; rechallenge was not done.
Expectedness	Expected - urticaria is listed in the product labelling of amoxicillin-clavulanate.

SECTION D - REPORTER DETAILS

Reporter	Abarna
Qualification	B.Pharm
Contact	To be added by reporter
Date of report	To be added by reporter

CASE NARRATIVE

A 42-year-old woman was prescribed amoxicillin-clavulanic acid 625 mg twice daily for acute bacterial sinusitis. She also took paracetamol as needed for headache. On Day 3 she developed an itchy, raised rash on the trunk and arms with mild facial

swelling. She had no breathing difficulty or low blood pressure. The suspect drug was stopped and she was given cetirizine. The rash resolved fully within 3 days of withdrawal. She had no prior drug allergy. The event was assessed as non-serious and expected. WHO-UMC causality: Probable. Follow-up is not required.

Fictional case for internship practice only.
